sentence each.

duplicate words.

1 0 1

'how', 'further', 'was', 'here', 'than'}

frequency.

advancements in machine learning, many organizations have begun applying natural language processing for translation, chatbots and candidate filtering. Without further delay let's dive into some code. To start, we'll import the

necessary libraries. import pandas as pd

from sklearn.feature_extraction.text import TfidfVectorizer

```
In this article, we'll be working with two simple documents containing one
```

documentA = 'the man went out for a walk'

documentB = 'the children sat around the fire'

```
Machine learning algorithms cannot work with raw text directly. Rather,
```

processing, a common technique for extracting features from text is to place

the text must be converted into vectors of numbers. In natural language

all of the words that occur in the text in a bucket. This aproach is called a bag of words model or BoW for short. It's referred to as a "bag" of words because any information about the structure of the sentence is lost. bagOfWordsA = documentA.split(' ') bagOfWordsB = documentB.split(' ')

uniqueWords = set(bagOfWordsA).union(set(bagOfWordsB))

Next, we'll create a dictionary of words and their occurence for each

By casting the bag of words to a set, we can automatically remove any

numOfWordsA = dict.fromkeys(uniqueWords, 0) for word in bagOfWordsA:

document in the corpus (collection of documents).

```
numOfWordsA[word] += 1
numOfWordsB = dict.fromkeys(uniqueWords, 0)
for word in bagOfWordsB:
   numOfWordsB[word] += 1
        a around children fire for man out sat the walk went
      0 1 0
```

Another problem with the bag of words approach is that it doesn't account

for noise. In other words, certain words are used to formulate sentences but

do not add any semantic meaning to the text. For example, the most

commonly used word in the english language is *the* which represents 7% of all words written or spoken. You couldn't make deduce anything about a text given the fact that it contains the word the. On the other hand, words like **good** and **awesome** could be used to determine whether a rating was positive or not. In natural language processing, useless words are referred to as stop words. The python **natural language toolkit** library provides a list of english stop words.

from nltk.corpus import stopwords stopwords.words('english')

```
('ourselves', 'hers', 'between', 'yourself', 'but', 'again', 'there', 'about', 'once', 'during', 'out', 'very', 'having', 'with', 'they', 'own', 'an', 'be',
'some', 'for', 'do', 'its', 'yours', 'such', 'into', 'of', 'most', 'itself', 'other', 'off', 'is', 's', 'am', 'or', 'who', 'as', 'from', 'him', 'each', 'the', 'them-
selves', 'until', 'below', 'are', 'we', 'these', 'your', 'his', 'through', 'don', 'nor', 'me', 'were', 'her', 'more', 'himself', 'this', 'down', 'should',
'our', 'their', 'while', 'above', 'both', 'up', 'to', 'ours', 'had', 'she', 'all', 'no', 'when', 'at', 'any', 'before', 'them', 'same', 'and', 'been', 'have', 'in'
'will', 'on', 'does', 'yourselves', 'then', 'that', 'because', 'what', 'over', 'why', 'so', 'can', 'did', 'not', 'now', 'under', 'he', 'you', 'herself', 'has',
'just', 'where', 'too', 'only', 'myself', 'which', 'those', 'i', 'after', 'few', 'whom', 't', 'being', 'if', 'theirs', 'my', 'against', 'a', 'by', 'doing', 'it',
```

Term Frequency (TF) The number of times a word appears in a document divded by the total number of words in the document. Every document has its own term

Often times, when building a model with the goal of understanding text,

you'll see all of stop words being removed. Another strategy is to score the

 $tf_{i,j} = \frac{n_{i,j}}{\sum_{k} n_{i,j}}$

tfA = computeTF(numOfWordsA, bagOfWordsA) tfB = computeTF(numOfWordsB, bagOfWordsB)

The following code implements term frequency in python.

relative importance of words using TF-IDF.

```
def computeTF(wordDict, bagOfWords):
   tfDict = {}
   bagOfWordsCount = len(bagOfWords)
   for word, count in wordDict.items():
       tfDict[word] = count / float(bagOfWordsCount)
   return tfDict
```

The following lines compute the term frequency for each of our documents.

Inverse Data Frequency (IDF) The log of the number of documents divided by the number of documents

that contain the word w. Inverse data frequency determines the weight of

```
rare words across all documents in the corpus.
                  idf(w) = log(\frac{N}{df_t})
```

import math N = len(documents)idfDict = dict.fromkeys(documents[0].keys(), 0) for document in documents:

The following code implements inverse data frequency in python.

for word, val in document.items():

idfDict[word] += 1

idfDict[word] = math.log(N / float(val))

def computeIDF(documents):

return idfDict

if val > 0:

for word, val in idfDict.items():

def computeTFIDF(tfBagOfWords, idfs):

df = pd.DataFrame([tfidfA, tfidfB])

vectorizer = TfidfVectorizer()

for word, val in tfBagOfWords.items(): tfidf[word] = val * idfs[word]

tfidf = {}

return tfidf

```
The IDF is computed once for all documents.
  idfs = computeIDF([numOfWordsA, numOfWordsB])
Lastly, the TF-IDF is simply the TF multiplied by IDF.
```

 $w_{i,j} = t f_{i,j} \times \log\left(\frac{N}{df_i}\right)$

Rather than manually implementing TF-IDF ourselves, we could use the class provided by sklearn.

vectors = vectorizer.fit transform([documentA, documentB])

feature_names = vectorizer.get_feature_names()

for the word *the* would be greatly reduced.

Machine Learning

```
dense = vectors.todense()
denselist = dense.tolist()
df = pd.DataFrame(denselist, columns=feature names)
```
